INTRODUCTION

1.1. RESEARCH QUESTIONS

Main question:

How can the nD -Laplace algorithm be applied in training privacy-preserving clustering algorithms on distributed n -dimensional data?

1. RQ1: How can 2D-Laplace be used to protect the data privacy of 2-dimensional data which is employed for training clustering algorithms?
2. RQ2: How can 3D-Laplace be extended to protect the data privacy of n -dimensional data which is employed for training clustering algorithms?
3. RQ3: What is the impact of different privacy budgets, dataset properties, and other clustering algorithms on the research conducted for research question 2?

2

LITERATURE REVIEW

This chapter lays out the theoretical foundation of this work. To review the past literature, it is first necessary to gather the required knowledge for it.

2.1. DIFFERENTIAL PRIVACY

ND-LAPLACE

3.1. 2D-LAPLACE

The theory for this subject is heavily inspired by the paper that was written by Andrés et al. [Andrés et al., 2012]. This notion of **Geo-indistinguishability (GI)** was introduced to solve the issue of privacy and location data. It offers an alternative approach for differential privacy by adding noise to the location locally before sending it to a location-based system (LBS) like Google maps. This section starts with an introduction to mathematics for the planar and polar Laplace algorithm. For each of the different subsections, we visualize and explain open challenges and theoretic for applying them for clustering.

MATH SYMBOLS

X Set of locations for a user. (R^2).

Z For every $x \in X$ a perturbed location $z \in Z$ is reported..

ϵ Defined as $\epsilon = l/r$.

θ Angle.

l Privacy level.

r Radius.

GEO-INDISTINGUISHABILITY

As mentioned in the previous section, the **GI** method can be applied to preserve the privacy using a differential privacy method specific to spatial data. The formula to measure if an algorithm preserves ϵ -geo-indistinguishability can be expressed as [Andrés et al., 2012]:

$$K(x)(y) \leq e^{\epsilon * d(x, x')} * K(x')(y) \quad (3.1)$$

Where K is a probability method reporting $x, x' \in X$ as $z \in Z$. The idea of this algorithm looks a lot like that of differential privacy using the La Place method; but includes distance. The intuition for this is that it displays the distinguishability level between two secret locations/points x and x' [Chatzikokolakis et al., 2015]. An extension of this is called d_x -privacy and is a more general notation of distance-aware differential privacy. Their definition for **GI** is, therefore, d_2 -privacy, but is essentially the same as the proof provided for **GI**.

3.1.1. PLANAR AND POLAR LAPLACE

The idea of planar Laplace is to generate an area around $x_0 \in X$ according to the multivariate Laplace distribution. The mechanism of planar Laplace is a modification of the Laplace algorithm to support distance [Andrés et al., 2012]. This distance method $dist(x, x)$ is defined as the Euclidean distance between two points or sets. Recalling the definition of Laplace, this method $|x - x|$ is replaced by the distance metric. Hence, the definition of the Probability Density Function (pdf) by Andrés et al. is:

$$\frac{\epsilon^2}{2 * \pi} e(-\epsilon d(x_0, x)) \quad (3.2)$$

Which is the likelihood a generated point $z \in Z$ is close to x_0 . The method works for Cartesian coordinates but was modified to support polar coordinates by including θ . So each point is reflected as (r, θ) and can be modified by using a slight modification to work for polar Laplace. A point $z \in Z$ where $z = (r, \theta)$ is randomly generated using two separate methods for calculating r and θ .

Figure 3.1: Representation of the generated $z = r\theta$ and original point x_0 .

Calculating r : This variable is described as $dist(x_0, z)$ and can be randomly drawn by inverting the CDF ([Link](#)) for the Laplace distribution:

$$C_\epsilon^{-1}(p) = -\frac{1}{\epsilon} (W_{-1}(\frac{p-1}{e}) + 1) \quad (3.3)$$

For this equation, W_{-1} is a Lambert W function with -1 branch. The Lambert w function, also called the product logarithm is defined as $W(x)e^{W(x)} = x$ [Lehtonen, 2016]. The purpose of the Lambert w function is to invert the CDF of the Laplace distribution to generate random noise for one of the coordinates (r) using the random value of p .

Calculating θ : The other coordinate (θ) is defined as a random number $[0, 2\pi]$.

To visualize these methods it is necessary to convert the polar coordinates for $z = (r, \theta)$ back to a plane (x, y) . This is described as step 4 of the planar Laplace algorithm [Andrés et al., 2012] and visualized using figure 1.

We highlight the CDF function for assessing if the probability of a random point falls between 0 and r :

$$C_\epsilon(r) = D_{\epsilon, R}(p) dp = \int_0^r 1 - (1 + \epsilon r) e^{-\epsilon r} \quad (3.4)$$

Can be moved to appendix

Figure 3.2: Representation of converting the perturbed point $z = (r, \theta)$ to a point z_x, z_y

3.1.2. TRUNCATION

Because we have a finite space, it can be possible the perturbed points are off-graph (outside the given domain). The solution was described in step 5 of the Laplacian mechanism for 2D space. This explains the idea of remapping to the closest admissible location in set A. For which $A \subset \mathbb{R}$, where A is the set of admissible locations [Andrés et al., 2012]. This is also described by chatzikokolakis et al, who also describes a method to do it. When a perturbed point z is located at the sea or in water, it is easily distinguishable as a fake location. They introduce a method to check this and efficiently remap to a nearby location.

Describe the method

Analyze other methods

3.1.3. OPTIMIZING FOR CLUSTERING

The decision of the parameters for the algorithm is straightforward as it depends on the ϵ . This constant is calculated by defining the radius r and the desired level of privacy l and ϵ is calculated using l/r . The l is a predefined constant $l \in \mathbb{R}^+$ but usually will be below 10. For geographical data, the r is straightforward and can be configured by using meters as a unit of measure. Therefore, $r = 200$ corresponds to a radius of 200m around point x_0 . So, regarding clustering, it is a challenge to define a reasonable radius.

The ϵ can be considered the inverse unit of r [Andrés et al., 2012]. A radius can be defined per-use case based on how crowded a place is [Chatzikokolakis et al., 2015].

Give the algorithm

A drawn area as shown in ?? can be expressed as a perturbation area P_{area} [Yan et al., 2022]. This metric was formulated as:

$$P_{area} = \left\{ center = x_0, radius = \frac{1}{N} \times \sum_{i=1}^N r_i \right\} \quad (3.5)$$

The method loops through each perturbed point r on center x_0 (recall ??) and calculates the Euclidean distance for an n amount of perturbation points. Although the method does not contribute to the Laplace algorithm, it is useful for visualization purposes.

3.2. 3D-LAPLACE

Is considered for research question 3

4

METHODOLOGY

To gain insights into the proposed methods for researching the appliance of (ND)-Laplace for cluster algorithms we conducted experiments. The experiment results are used to evaluate our method against other literature. In this chapter we explain:

1. Datasets
2. Environmental setup.
3. For each research question: Description of the different experiments.
4. For each research question: Results.

4.1. DATASETS

For this research, we will use a synthetic dataset for all three research questions.

Records	Centers	Dimensions	Standard deviation	Research
200	4	2	0.60	RQ 1
200	4	3	0.60	RQ 2
200	4	5	0.60	RQ 2

Research question 3 uses a "real-world" dataset to properly assess the different dataset properties that are the subject of this research question.

Describe datasets (RQ3)

4.2. ENVIRONMENTAL SETUP

For running the experiments we make use of 16GB ram memory and i7-10750H 2.6Ghz processor. The experiments are run using a Docker container which runs a pre-configured distribution of Linux Alpine. It includes a pre-installed Anaconda environment for python^{1,2}. We run the container using the dev-container feature for visual-studio code³. This allows us to create a reproducible experiment environment.

²tag: mcr.microsoft.com/devcontainers/anaconda:0-3

³<https://code.visualstudio.com/docs/devcontainers/containers>

4.2.1. LIBRARIES & CODE VERSIONS

We use python version 3.9.13 with Jupyter notebook for creating a reproducible experimental environment. The packages for python are:

1. Scikit-learn: 1.0.*
2. Yellow-brick: 1.5
3. Numpy: 1.24.*
4. Pandas: 1.4.*
5. Seaborn: 0.11.*
6. Mathplotlib: 3.5.*

4.3. METHODS

This section explains what methods/ algorithms we used and how we evaluate them.

4.3.1. CLUSTERING METHODS

Exact parameters we used for the algorithms

Which algorithms we used

4.3.2. EVALUATION

With differential privacy, it is a trade-off of utility versus privacy. Therefore, for the evaluation of the 2D/3D-Laplace algorithms, we compare both criteria to achieve a consensus between utility and privacy.

UTILITY

The utility of the cluster algorithm is decided by calculating the **Adjusted Mutual Information (AMI)** between the baseline cluster algorithms. The clustering algorithm is trained using the plain data and functions as the ground truth [Sun et al., 2019; ?]. Because of this, we are being able to calculate the **AMI** and compare the centroids between the non-private and privately trained clusters. To reduce the possible bias of results we executed them 10 times for multiple privacy budgets and report the average for each [Huang et al., 2021].

Explain why AMI and not another

The second way to measure utility is to calculate the error between the non-private and perturbed data [Huang et al., 2021; Sun et al., 2019; Xia et al., 2020]. There are several methods to do this (See 2.2.2), but we use the **Average Estimated Error (AEE)**. As with **AMI** we run the calculations for multiple privacy budgets 10 times and report the average for each budget.

Explain why AEE and not RE

PRIVACY

The most important one here is the preserving of **GI**. This validates that we applied the algorithms in the right way and automatically inherit the strong privacy guarantees provided by **GI (3.1)**. A disadvantage of this method is that it cannot be used to achieve a clear representation of privacy (it is either "yes" or "no"). Therefore, we also calculate the average Euclidean distance between the non-private and perturbed data.

4.3.3. RESEARCH QUESTION 1

TRUNCATION:

We explained the theory for truncation earlier in paragraph 3.1.2. The methods proposed work correctly for a geographic map where other (historic) locations for remapping are available.

However, it is difficult to apply this to data clustering. The number of data points is not known beforehand, so we may remap to a location that is too far away. This way we lose important clusters, which hurts the clustering. Also, the truncation threshold is so clear (the points are outside the known 2D domain), that we do not have to rely on historical data for remapping. Our algorithm can be much simpler by re-calculating the noise until it will be within the domain: This algorithm uses x_{min} and x_{max} to re-calculate the points

Algorithm 1 Truncation algorithm ($T(\min, \max, x_0, z)$) for clustering with planar Laplace

Ensure: z

$x_1, y_1 \leftarrow x_{min}$

$x_2, y_2 \leftarrow x_{max}$

$z_x, z_y \leftarrow z$

if $x_1 < z_x < x_2$ and $y_1 < z_y < y_2$ **then**

return z

else

$x, y \leftarrow x_0$

$z_2 \leftarrow LP(\epsilon, x, y)$

return $T(x_{min}, x_{max}, x_0, z_2)$

end if

▷ See formula 3.3.
▷ Rerun recursively

within the domain using respectively the minimum X/Y and maximum X/Y. An example of this is visualized:

Figure 4.1: Representation of the remapping algorithm for clustering for points z_3 and z_4

PROBABILITY METRIC $K(x)(Z)$

Explain the probability metric K we used

ALGORITHM

The full algorithm for the perturbation:

Algorithm 2 Full algorithm for perturbing cluster data based on planar/2D-Laplace [Andrés et al., 2012]

Require: $x \in X$ ▷ 2D array of points
Require: $l \in R^+$
Ensure: $z \in Z$ ▷ 2D array of perturbed points
 $r = \frac{\sigma}{2}$ ▷ formula 4.1
 $\epsilon = \frac{l}{r}$ ▷ Calculating privacy budget [Andrés et al., 2012]
 $x_{min} \leftarrow \min(X)$
 $x_{max} \leftarrow \max(X)$
 $Z \leftarrow []$
for $point_i \in X$ **do** ▷ Random noise for θ
 $\theta \leftarrow [0, \pi/2]$
 $p \leftarrow [0, 1]$
 $z_i \leftarrow C_\epsilon^{-1}(p)$ ▷ formula 3.2
 $z_i \leftarrow T(x_{min}, x_{max}, point_i, z_i)$ ▷ algorithm 1.
 $x_{perturbed} \leftarrow point_{i_x} + (z_{i_x} * \cos(\theta))$ ▷ add noise to x-coordinate
 $y_{perturbed} \leftarrow point_{i_y} + (z_{i_y} * \sin(\theta))$ ▷ add noise to y-coordinate
 append $x_{perturbed}, y_{perturbed}$ to Z
end for
return Z

GLOSSARY

- Adjusted Mutual Information** Comparable with **Adjusted Rand Index** this algorithm is modified to account to chance. This means it accounts for a higher MI for a higher amount of clusters between two cluster algorithms. Therefore, the calculations are strongly influenced by that of **Adjusted Rand Index** [?]. . 6, 10
- Adjusted Rand Index** The Rand Index is improved and adjusted for chance [?]. This algorithm takes also into consideration the number of clusters and can be used to also compare different cluster algorithms [?]. i, 6
- Average Estimation Error** This is the difference between an estimated value and the real value.. 6, 10
- Bit Vector** List or array to store several bits.. 6
- Calinski-Harabasz Index** This is a way to measure the similarity of clusters [?]. It tells how well the clusters are separated from each other and how well the points are grouped.. 6
- Mutual Information** This metric can be used to explain the amount of information about a random variable if compared to another random variable. Therefore, it can also be used to compare two cluster similarities.. ii, 6

Normalized Mutual Information The normalized version is a scaled version of **Mutual Information** to always be a value between 0 (no correlation) and 1 (perfect correlation). This version of **Mutual Information** is not adjusted and therefore highly influenced by cluster amount [?]. So it suffers the same issue as with **Mutual Information**.. 6

Rand Index Compares the similarity between two clusters by comparing all pairs. It can therefore be used to measure the performance between two clustering algorithms [?]. 6
